

Customer Data Management in the Insurance Industry

BUSINESS PAINS

- ▶ The IT systems in many insurance companies have steadily grown over the years, often resulting in heterogeneous system landscapes. Individually implemented solutions for specific problems make the system landscape even more heterogeneous and obscure.
- ▶ There is no overall customer view covering all insurance divisions. It's often unknown whether the same customer also has other insurance policies with the same company.
- ▶ Data silos: The same customer is often registered in different systems.
- ▶ Solvency II requires complete and accurate data as a basis for the insurer to make calculations and reports

ADVANTAGES

- ▶ A 360° view of the insured party = Consolidation of information from fragmented systems and from every division and channel to create an all-encompassing view.
- ▶ A single source where all existing data is readily available, e.g., for further analysis or risk calculation.
- ▶ The availability of all relevant information provides improved possibilities for offering the insured party other suitable insurances
- ▶ A lean management solution that doesn't require a complex integration project

CHALLENGE

In many cases, customers have several insurance contacts with the same insurance company. But the company itself is often unaware, because different people deal with the same customer, and each one uses a different IT system and keeps data in different customer databanks. Over the years, heterogeneous systems develop and make a uniform view of the customer increasingly difficult. Much information is duplicated or triplicated, and centralised data storage and a company-wide data model are usually both missing.

Long-term customer loyalty, efficient policy administration, reliable analyses for risk management, finalising contracts, and optimal consultation and service for existing customers,

are only possible when a customer view across insurance divisions is available. Only high quality data that can be meaningfully linked across all insurance divisions enables perfect customer service - and the opportunity for gaining new customers.

Implementation of European Union Solvency II guidelines involves high demands on venture capital, and presents the branch with particular challenges. Solvency II requires that insurance companies make their calculations and reports based upon fully-complete, high quality data: Even relatively minor deviations in the output data can have considerable effects on risk evaluation.

SOLUTION

Uniserv Smart Customer MDM is the perfect solution for efficiently dealing with your customer data. Smart Customer MDM merges customer data from all available channels to provide a holistic view of the customer, and can extract customer master data from the widest range of heterogeneous data sources.

But before this information is merged to an all-encompassing customer view, Uniserv's data quality tools ensure that it is cleansed, structured, and absolutely up-to-date. Data quality mechanisms take effect immediately during initial data collection and the consistency of customer data is guaranteed from all sources. Whenever an alteration is made to a particular customer record in any system, this alteration is identified, processed, and passed on to the other systems. Smart Customer MDM fulfils all requirements of Solvency II regarding the quality of company data.

Smart Customer MDM helps to avoid redundant items in your data storage and clearly identifies your customer in all company processes, systems and departments. This quality-

improved and optimised data is merged to form a Golden Record, containing the most complete, correct and up-to-date information known about a particular insured party. External data, such as contractual data, claims data, accounting data, actuary information, obituaries and Robinson lists, as well as data from other external suppliers, can all be imported simply, cleanly and fast.

Implementation of Uniserv's Smart Customer MDM will improve productivity throughout your entire company. It rationalises working processes, such as invoicing, damage claims, and the distribution of annual business reports. Smart Customer MDM doesn't require a complex integration project, and no alterations have to be made to any existing data models. Its implementation is based upon the principles of Lean Integration, therefore costs are kept low and the project remains lean. Smart Customer MDM can be implemented fast; and together with its high level of scalability and our targeted data handling, it will provide tangible added value after just three months. Your ROI will soon be apparent.
